1. Explain the Drupal architecture.

Drupal follows a **modular architecture** built on top of **Symfony components**.

Main layers:

1. **Request Layer** – Handles HTTP requests using Symfony HttpKernel.
2. **Routing Layer** – `routing.yml` defines routes and controllers.
3. **Controller Layer** – Processes logic and returns render arrays.
4. **Service Layer** – Business logic implemented through services.
5. **Entity API** – Handles structured data like nodes, taxonomy, users.
6. **Render System** – Converts render arrays into HTML.
7. **Theme Layer** – Twig templates render final output.

Key advantages:

- Highly extensible
- Decoupled architecture
- Service container dependency injection

2. What are the key differences between Drupal 7 and Drupal 8/9/10?

Feature	Drupal 7	Drupal 8+
Architecture	Procedural	OOP + Symfony
Templating	PHPTemplate	Twig
Routing	hook_menu	routing.yml
Configuration	Database	YAML config
Dependency Management	None	Composer
Services	Not available	Symfony Service Container

Drupal 8+ introduced **modern PHP practices and enterprise-grade architecture**.

3. What is Drupal Service Container?

Drupal uses **Symfony Dependency Injection Container** to manage services.

Services are reusable objects defined in:

module.services.yml

Example:

```
services:
 my_module.custom_service:
   class: Drupal\my_module\Service\CustomService
```

Usage via dependency injection:

```
public function __construct(CustomService $service) {
  $this->service = $service;
}
```

Benefits:

- Loose coupling
- Testability
- Reusable architecture

4. What is the Drupal Entity API?

Entity API manages structured data objects.

Common entity types:

- Node
- User
- Taxonomy
- Media
- Paragraphs
- Custom entities

Entities support:

- Field API
- Revisioning
- Translations
- Access control

Example entity load:

```
$node = \Drupal\node\Entity\Node::load(1);
```

For large systems, **custom content entities** are often created.

5. Explain Drupal Configuration Management.

Drupal stores configuration in **YAML files**.

Two environments:

Environment	Purpose
Active	Database
Sync	YAML files

Commands:

```
drush config-export
drush config-import
```

Benefits:

- Version control friendly
- Environment consistency
- Dev → Stage → Prod deployments

6. What are Render Arrays?

Render arrays are structured arrays used by Drupal to build HTML.

Example:

```
$build['title'] = [
'#type' => 'markup',
'#markup' => 'Hello World'
];
```

Advantages:

- Caching metadata
- Lazy loading
- Secure rendering

7. Explain Drupal Caching layers.

Drupal has **multiple caching layers**.

1. Page Cache
2. Dynamic Page Cache
3. Render Cache
4. Twig Cache
5. Entity Cache
6. Database Cache
7. Reverse Proxy Cache (Varnish/CDN)

Example configuration:

Redis
Memcached
Varnish
Cloudflare CDN

For enterprise sites, using **Redis + Varnish + CDN** is common.

8. How would you improve Drupal site performance?

Performance optimization includes:

Application Level

- Enable render caching
- Optimize Views queries
- Use lazy builders
- Reduce unnecessary modules

Infrastructure Level

- Redis caching
- Varnish reverse proxy
- CDN
- Database optimization

Frontend

- Aggregation
- Lazy loading
- Image optimization

9. What are Drupal Hooks?

Hooks allow modules to **alter Drupal behavior**.

Example:

hook_form_alter()
hook_preprocess_node()
hook_entity_insert()

Example:

```
function mymodule_form_alter(&$form) {
 $form['submit']['#value'] = 'Submit Form';
}
```

Hooks are **event-driven extension points**.

10. What is Drupal Plugin System?

Plugins are reusable components managed by **plugin managers**.

Examples:

- Block plugins
- Field formatters
- Field widgets
- Image effects
- Queue workers

Example block plugin:

```
class CustomBlock extends BlockBase {
 public function build() {
   return ['#markup' => 'Custom Block'];
 }
}
```

11. How do you design a scalable Drupal architecture?

Typical enterprise Drupal architecture:

```
Users
 |
CDN (Cloudflare)
 |
Load Balancer
 |
Web Servers (Drupal)
 |
Redis Cache
 |
Database Cluster
 |
Search Engine (Solr)
```

Best practices:

- Stateless application servers
- Horizontal scaling
- External caching
- CDN

12. How would you build a headless Drupal system?

Drupal can act as **backend CMS**.

API options:

- JSON:API
- REST API
- GraphQL

Architecture:

```
Drupal (Content API)
    |
React / Next.js
    |
Frontend UI
```

Benefits:

- Decoupled architecture
- Faster frontend
- Multi-channel delivery

1️⃣ REST API

REST (Representational State Transfer) is an **architectural style** for building APIs over HTTP.

Key Characteristics

- Uses **standard HTTP methods**
  - `GET` – retrieve data
  - `POST` – create
  - `PUT/PATCH` – update
  - `DELETE` – remove
- Uses **resource-based URLs**

Example:

GET /users/10

GET /users/10/posts

Response (usually JSON):

```
{
 "id": 10,
 "name": "John",
```

```
 "email": "john@email.com"
}
```

Pros

✔ Simple and widely used
✔ Works well with caching
✔ Easy to understand

Cons

❌ Over-fetching or under-fetching data
❌ Multiple requests often needed

2️⃣ JSON:API

JSON:API is a specification (standard format) for building REST APIs using JSON.

It **defines rules for how requests and responses should look**.

So think of it as:

REST = architecture
JSON:API = standardized format for REST responses

Key Features

- Standard structure for responses
- Supports **relationships**
- Built-in **pagination, filtering, sorting**
- Reduces number of API calls via **included resources**

Example response:

```
{
 "data": {
   "type": "users",
   "id": "10",
   "attributes": {
     "name": "John"
   },
   "relationships": {
     "posts": {
       "data": [{ "type": "posts", "id": "5" }]
     }
   }
 }
}
```

Pros

✔ Consistent API structure
✔ Handles relationships well
✔ Great for large applications

Cons

❌ Response format can be verbose
❌ Learning curve

Common in **Drupal APIs**.

3️⃣ GraphQL

GraphQL is a query language for APIs created by Facebook.

Instead of multiple endpoints, **GraphQL uses a single endpoint** and lets the client request exactly the data it needs.

Example query:

```
{
 user(id: 10) {
   name
   email
   posts {
     title
   }
 }
}
```

Response:

```
{
 "data": {
   "user": {
     "name": "John",
     "email": "john@email.com",
     "posts": [
       { "title": "First post" }
     ]
   }
 }
}
```

Pros

✔ No over-fetching or under-fetching

✔ Single endpoint
✔ Flexible queries

Cons

❌ Harder caching
❌ More complex backend
❌ Security considerations

📊 Quick Comparison

Feature	REST API	JSON:API	GraphQL
Type	Architecture	REST specification	Query language
Endpoints	Multiple	Multiple	Single
Data fetching	Fixed response	Standardized response	Client decides
Over-fetching	Possible	Reduced	None
Flexibility	Medium	Medium	Very high
Learning curve	Easy	Medium	Higher

✅ **Simple way to remember**

- **REST** → Standard API design
- **JSON:API** → Standard format for REST responses
- **GraphQL** → Client-driven data querying

13. What is Drupal Queue API?

Queue API handles background tasks.

Example use cases:

- Sending emails
- Content indexing
- Data imports

Example:

```
$queue = \Drupal::queue('my_queue');
$queue->createItem($data);
```

Workers process items asynchronously.

14. How do you secure a Drupal application?

Security best practices:

1. Regular Drupal core updates
2. Security module monitoring
3. Input sanitization
4. Proper permissions
5. HTTPS everywhere
6. Secure coding standards

Use:

- **Drupal Security Team advisories**
- **Composer-based updates**

15. How would you design a multi-site Drupal architecture?

Drupal supports **multi-site installations**.

Structure:

```
sites/
  site1.com
  site2.com
  site3.com
```

Shared:

- Codebase
- Modules

- Themes

Separate:

- Database
- Configuration

Useful for **large enterprises managing multiple brands**.

16. What is the Drupal Paragraphs module and why use it?

Paragraphs allow **component-based content modeling**.

Editors can build pages using components like:

- Hero banner
- Image gallery
- CTA block
- Text section

Benefits:

- Flexible content
- Reusable components
- Page builder capability

17. How would you migrate content into Drupal?

Drupal Migration API.

Modules:

- migrate
- migrate_plus
- migrate_tools

Example migration:

source → transform → destination

Supports:

- CSV
- JSON
- XML
- Database migrations
- Drupal 7 → Drupal 10

18. What DevOps practices do you implement for Drupal?

Typical pipeline:

```
Git Repository
   |
CI/CD (GitHub Actions / Jenkins)
   |
Build with Composer
   |
Automated Tests
   |
Deploy to Environment
```

Tools:

- Docker
- Kubernetes
- GitHub Actions
- Terraform
- Ansible

19. How do you handle Drupal deployments?

Deployment process:

1. Code deployment via Git
2. Composer install
3. Config import

```
drush cim -y
```

4. Database updates

```
drush updb
```

5. Cache rebuild

```
drush cr
```

Use **automated CI/CD pipelines**.

20. As a Solution Architect, how do you approach a new Drupal project?

Architecture steps:

1. Requirement analysis

2. Content modeling
3. System architecture design
4. Module selection strategy
5. Performance strategy
6. Security planning
7. Deployment architecture

Deliverables include:

- Architecture diagrams
- Content models
- API strategy
- Infrastructure plan

Focus is on **scalability, maintainability, and performance**.

1. Design a Drupal platform for 10 million users.

Architecture should include:

```
Users
  |
CDN (Cloudflare/Akamai)
  |
Load Balancer
  |
Drupal Web Servers (Autoscaling)
  |
Redis / Memcached
  |
Database Cluster (MySQL/Aurora)
  |
Search Engine (Solr/Elastic)
```

Key strategies:

- CDN caching
- Redis for render/entity cache
- Varnish reverse proxy
- Horizontal scaling
- Database read replicas

2. A Drupal site becomes slow under heavy traffic. How would you troubleshoot?

Steps:

1. Check **NewRelic / Datadog traces**
2. Identify **slow queries**

3. Analyze **Drupal Views**
4. Enable **render caching**
5. Move cache to **Redis**
6. Add **reverse proxy cache**

Typical bottlenecks:

- Uncached Views
- Heavy entity queries
- Large field tables
- Slow external APIs

3. Design a Headless Drupal architecture.

```
Drupal (Content Management)
   |
JSON:API / GraphQL
   |
API Gateway
   |
Frontend (React / Next.js / Mobile Apps)
```

Advantages:

- Faster frontend
- Multi-channel delivery
- Independent scaling

4. Design Drupal for a global multilingual website.

Use:

- Drupal **Content Translation**
- **Language negotiation**
- CDN edge caching

Architecture:

```
Users (Global)
    |
CDN (Geo caching)
    |
Drupal Cluster
    |
Shared Database
```

5. Drupal site must serve multiple brands. What architecture would you use?

Two options:

Option 1: Multisite

Single codebase
Multiple databases

Option 2: Distribution

Shared modules
Brand-specific themes

Best for **enterprise organizations**.

6. Design Drupal media platform handling millions of videos.

```
Drupal CMS
   |
Media Metadata
   |
Object Storage (S3)
   |
Video Processing (Lambda)
   |
CDN (CloudFront)
```

Use:

- Media module
- S3 file storage
- CDN streaming

7. How would you integrate Drupal with microservices?

Use:

- REST APIs
- Event queues
- Message brokers

Architecture:

```
Drupal
 |
API Gateway
 |
Microservices
```

Example services:

- Payments
- Search
- User analytics

8. How would you design Drupal CI/CD pipeline?

```
Developer
 |
Git Repository
 |
CI Pipeline
 |
Composer Build
 |
Automated Tests
 |
Deployment
```

Tools:

- GitHub Actions
- Jenkins
- GitLab CI

9. Design search architecture for large Drupal site.

Use **Apache Solr / Elasticsearch**.

```
Drupal
 |
Search API Module
 |
Solr Cluster
```

Benefits:

- Faster search
- Faceted navigation
- Full-text indexing

10. How do you ensure high availability?

Use:

- Multi-AZ infrastructure
- Load balancers
- Auto scaling groups
- Database replicas

11. How do you design Drupal for API-first architecture?

Use:

- JSON:API
- GraphQL
- API Gateway
- Rate limiting

12. How do you reduce Drupal deployment risks?

Use:

- Feature flags
- Blue/Green deployments
- Automated testing
- Config management

13. How would you migrate legacy CMS to Drupal?

Steps:

1. Content audit
2. Content model design
3. Migration scripts
4. Validation

Tools:

- Migrate API
- migrate_tools

14. How would you optimize Drupal database?

Strategies:

- Query indexing
- Table cleanup
- Reduce field tables
- Cache heavy queries

15. Design Drupal analytics architecture.

```
Drupal
  |
Event Tracking
  |
Kafka
```

|
Analytics Platform

Apache Kafka is a **distributed system used to send, store, and process real-time data streams between applications**.

In simple words:

👉 **Kafka is like a high-speed message pipeline that lets different systems share data instantly.**

It is commonly used when **many systems need to send and receive large amounts of data continuously**.

Simple Real-World Analogy

Think of **Kafka like a post office** 📬

1. **Producer** → Person sending letters
2. **Kafka (broker)** → Post office that receives and organizes letters
3. **Consumer** → Person receiving letters

Messages are stored temporarily so multiple people can read them.

Basic Components of Kafka

Component	Meaning
Producer	Application that sends data
Kafka Broker	Kafka server that stores messages
Topic	Category or stream of messages
Consumer	Application that reads messages
Partition	Splits data for scalability

Example: Food Delivery App

Imagine an app like **Uber Eats / DoorDash**.

When a user places an order:

Step 1 — Producer sends message

The **order service** sends an event to Kafka.

Topic: orders
Message: "Order #2456 placed by User 32"

Step 2 — Kafka stores the event

Kafka stores the message inside a **topic called** `orders`.

Step 3 — Multiple services read the message

Different systems consume the same message:

Consumer	Action
Payment Service	Process payment
Restaurant Service	Send order to restaurant
Delivery Service	Assign driver
Notification Service	Send confirmation SMS

All these systems read the **same Kafka message independently**.

Simple Flow Diagram

```
User places order
      |
      v
  Producer (Order Service)
      |
      v
    Kafka Topic: "orders"
      |
 -----------------------------
 |     |        |         |
Payment  Delivery  Email   Analytics
Service  Service   Service   System
```

Why Companies Use Kafka

✔ Handles **millions of messages per second**
✔ Works in **real-time**
✔ Highly **scalable**
✔ Reliable and fault-tolerant
✔ Multiple systems can read the same data

Real Companies Using Kafka

- Netflix
- LinkedIn (Kafka was originally built here)
- Uber
- Airbnb
- Spotify
- Amazon

Example in E-commerce

When someone buys a product:

Kafka sends events like:

order_created
payment_processed
inventory_updated
shipping_started
email_sent

Each microservice reacts to these events.

One-Line Summary

👉 **Apache Kafka is a real-time event streaming platform that lets multiple systems send and receive large amounts of data quickly and reliably.**

16. Design Drupal content hub.

Drupal acts as **central content repository** distributing content to:

- websites
- mobile apps
- kiosks

17. How would you handle millions of nodes?

Use:

- Solr search
- Redis caching
- Efficient Views queries

18. How would you scale Drupal infrastructure on AWS?

Use:

- EC2 autoscaling
- RDS
- ElasticCache Redis
- S3 storage
- CloudFront CDN

19. How do you monitor Drupal production?

Use:

- NewRelic
- Datadog
- Prometheus
- ELK logging

New Relic focuses on application performance monitoring, Datadog provides full-stack infrastructure and cloud monitoring, and Prometheus is an open-source metrics monitoring system widely used with Kubernetes. New Relic and Datadog are SaaS platforms with agents, while Prometheus uses a pull-based metrics collection model.

New Relic is a **monitoring and observability platform** used to track the **performance, health, and errors of applications, servers, and infrastructure in real time**.

In simple words:

👉 **New Relic helps developers see what is happening inside their application and quickly detect problems.**

It shows things like:

- Slow APIs
- Errors in code
- Server CPU/memory usage
- Database performance
- User experience

Simple Example

Imagine you run an **e-commerce website**.

A customer complains that **checkout is very slow**.

Without New Relic:

- You don't know where the problem is.

With New Relic:
You can see exactly where the issue is:

```
User → Web Server → API → Database
            ↑
      Slow SQL Query
```

New Relic shows:

- API response time
- Slow database queries
- Server load
- Error traces

So you can **quickly fix the issue**.

What New Relic Monitors

1️⃣ Application Performance Monitoring (APM)

Tracks application performance.

Example:

- API response time
- Code errors
- Slow functions
- Transaction traces

Example dashboard:

Average Response Time: 220ms

Error Rate: 0.5%

Throughput: 1200 requests/min

2️⃣ Infrastructure Monitoring

Tracks server health.

Example metrics:

- CPU usage
- Memory usage
- Disk space
- Network traffic

3️⃣ Log Monitoring

Collects logs from servers and applications.

Example log:

ERROR: Database connection timeout

Service: checkout-api

Time: 10:32 AM

4 Real User Monitoring (RUM)

Tracks **actual user experience**.

Shows:

- Page load time
- Browser performance
- Geographic user locations

Example:

US users → Page load: 1.2s

Europe users → Page load: 3.4s

5 Alerts & Notifications

You can configure alerts.

Example:

If API response time > 2 seconds

Send alert to Slack / Email

How New Relic Works

1 Install **New Relic agent** in your app/server

Example:

- Java agent
- Node.js agent
- PHP agent
- Python agent

2 Agent collects metrics

3 Data is sent to **New Relic cloud**

4️⃣ Dashboard displays analytics and alerts

Example Architecture

```
Users
 |
Web Application
 |
 | (New Relic Agent)
New Relic Platform
 |
 +---- Dashboards
 +---- Alerts
 +---- Logs
 +---- Performance metrics
```

Example in Drupal Website

New Relic can monitor:

- Drupal page load time
- Slow Drupal modules
- Database queries
- PHP errors
- Cache performance

Example issue detected:

Slow transaction:

node/123 page load

Cause:

Custom module → slow SQL query

Why Companies Use New Relic

✔ Real-time monitoring
✔ Quickly detect production issues
✔ Improve application performance
✔ Detailed debugging insights
✔ Works with cloud, containers, microservices

Datadog

What it focuses on

Infrastructure + cloud monitoring

Datadog is very strong for:

- Kubernetes
- Containers
- Cloud services (AWS, Azure, GCP)

Example

If a **Kubernetes cluster CPU spikes**, Datadog shows:

Cluster CPU usage: 95%

Pod causing spike: payment-service

Key Features

✔ Infrastructure monitoring
✔ Container monitoring
✔ Log management
✔ APM
✔ Security monitoring

Best Use Case

- Cloud-native applications
- Kubernetes environments
- DevOps teams

Prometheus

What it focuses on

Metrics monitoring

Prometheus is **open source** and widely used in **Kubernetes environments**.

Example

Prometheus collects metrics like:

http_requests_total

cpu_usage

memory_usage

And stores them in a **time-series database**.

Example query (PromQL):

rate(http_requests_total[5m])

Key Features

✔ Open source
✔ Powerful query language (PromQL)
✔ Time-series database
✔ Kubernetes integration
✔ Works with Grafana

Best Use Case

- Kubernetes monitoring
- DevOps metrics tracking
- Custom infrastructure metrics

20. How would you design enterprise Drupal governance?

Focus on:

- coding standards
- architecture reviews
- release processes

2️⃣ Drupal Architecture Diagrams (Enterprise Level)

These diagrams are commonly discussed in **architect interviews**.

Drupal Enterprise Architecture

```
      Users
        |
     CDN
        |
    Varnish
        |
  Load Balancer
        |
 -----------------
 |              |
Drupal App     Drupal App
Server         Server
```

```
  |              |
  -------Redis Cache-----
         |
     Database
      Cluster
         |
      Solr
```

Drupal + Redis + Solr Architecture

```
Users
 |
CDN
 |
Drupal Servers
 |
Redis (Caching)
 |
Solr (Search)
 |
MySQL Database
```

Kubernetes Drupal Architecture

```
Users
  |
  v
Load Balancer / Ingress
  |
  v
Kubernetes Cluster
  |
  +---------------------------+
  |                           |
Drupal Pods              Cache Layer
(Nginx + PHP-FPM)          Redis
  |
  v
Database (MySQL/Aurora)
  |
  v
Search Engine (Solr)
  |
  v
Storage (S3 / NFS)
```

Benefits:

- container orchestration
- automatic scaling
- high availability

Headless Drupal Architecture

```
Content Editors
      |
    Drupal
      |
  JSON API
      |
API Gateway
      |
React / Mobile Apps
```

Architecture

1. Explain Drupal bootstrap process.
2. Difference between **render cache vs dynamic page cache**.
3. When would you avoid using Views?
4. Explain Drupal request lifecycle.
5. Explain dependency injection advantages.

Performance

6. Why is Drupal slow sometimes?
7. How to cache personalized pages?
8. How to optimize large Views queries?
9. Difference between Redis vs Memcached in Drupal?
10. When to disable entity caching?

Backend

11. Difference between **Plugin vs Service**.
12. When should you create **custom entity types**?
13. Difference between **content entity and config entity**.
14. When to use **event subscribers** instead of hooks?
15. Explain **lazy builders**.

DevOps

16. Best Drupal deployment strategy.
17. How to handle config conflicts.
18. Composer dependency conflicts.
19. Automating Drupal testing.
20. Secrets management.

Advanced

21. How does Drupal render pipeline work?
22. Explain Twig caching.
23. How does Drupal access control work?
24. What causes cache invalidation issues?
25. Explain Drupal plugin discovery.

Migration

26. Biggest challenges in Drupal 7 → 10 migration.
27. How to migrate custom modules.
28. Migrating file systems.
29. Handling broken references.
30. Migration rollback strategies.

1. Design a High-Traffic Drupal Platform (10M+ Users)

Whiteboard Architecture

```
Users
 |
CDN (Cloudflare / Akamai)
 |
Varnish Cache
 |
Load Balancer
 |
Drupal App Servers (Auto Scaling)
 |
Redis / Memcached
 |
MySQL Database Cluster
 |
Solr / Elasticsearch
```

Key Points to Explain

- CDN edge caching
- Reverse proxy caching
- Horizontal scaling
- Redis caching
- Database read replicas

2. Design a Headless Drupal Architecture

Design a Drupal backend serving content to **web, mobile, and smart devices**.

Architecture

```
Editors
  |
Drupal CMS
  |
JSON:API / GraphQL
  |
API Gateway
  |
Frontend Apps
(React / Mobile)
```

Key Concepts

- decoupled CMS
- API versioning
- frontend caching
- content delivery

3. Design a Global Multilingual Drupal Platform

A company needs **content in 20 languages worldwide**.

Architecture

```
Global Users
    |
  Geo CDN
    |
Load Balancer
    |
Drupal Cluster
    |
Redis Cache
    |
Database
```

Explain

- language negotiation
- translation workflow
- CDN geo caching

4. Design a Drupal Content Hub

Drupal must distribute content to **multiple websites and mobile apps**.

Architecture

```
Editors
```

```
  |
Drupal Content Hub
  |
Content API
  |
Websites
Mobile Apps
Digital Displays
```

Explain

- central CMS
- API distribution
- content synchronization

5. Design a Drupal Media Platform (Millions of Images/Videos)

Architecture

```
Drupal CMS
  |
Media Metadata
  |
S3 Object Storage
  |
Video Processing Service
  |
CDN
```

Explain

- external file storage
- media optimization
- CDN streaming

6. Design Drupal Infrastructure on AWS

Whiteboard

```
CloudFront CDN
    |
AWS Load Balancer
    |
EC2 Auto Scaling
    |
Redis (ElasticCache)
    |
```

```
RDS MySQL Cluster
    |
Solr
```

Explain

- autoscaling
- caching
- managed services

7. Design a Drupal Multi-Site Platform for 50 Brands

Architecture

```
Shared Drupal Codebase
     |
 Multisite Setup
     |
Brand A DB
Brand B DB
Brand C DB
```

Explain

- shared modules
- isolated configuration
- theme customization

8. Design Drupal Search Architecture

Whiteboard

```
Drupal CMS
  |
Search API
  |
Solr / Elasticsearch Cluster
  |
Search Results
```

Explain

- indexing strategy
- faceted search
- performance improvements

9. Design a Scalable Drupal E-commerce Platform

Architecture

```
Users
 |
CDN
 |
Drupal Commerce
 |
Payment Services
 |
Order Microservices
 |
Database
```

Explain

- payment integration
- session handling
- cart performance

10. Design Drupal Deployment Pipeline

Whiteboard

```
Developer
  |
Git Repository
  |
CI/CD Pipeline
  |
Composer Build
  |
Automated Testing
  |
Deployment
```

Explain

- config management
- automated deployment
- rollback strategy

11. Design a Drupal Migration Strategy (D7 → D10)

Architecture

```
Drupal 7 Database
      |
```

Migration Scripts
|
Drupal Migration API
|
Drupal 10

Explain

- content audit
- migration phases
- validation

12. Design High-Availability Drupal System

Users
|
CDN
|
Load Balancer
|
Drupal Servers (Multi AZ)
|
Database Primary
|
Database Replica

Explain

- failover strategy
- disaster recovery

13. Design Drupal Integration with Microservices

Drupal CMS
|
API Gateway
|
Microservices
(Payments / Search / Analytics)

Explain

- service decoupling
- event-driven systems

14. Design Drupal Analytics Data Pipeline

Drupal Events
|

```
Message Queue (Kafka)
  |
Data Pipeline
  |
Analytics Platform
```

Explain

- event tracking
- big data processing

15. Design Kubernetes-Based Drupal Platform

```
Users
 |
Ingress Controller
 |
Kubernetes Cluster
 |       |
Drupal Pod Drupal Pod
 |       |
Redis     Solr
 |
Managed Database
```

Explain

- container orchestration
- scaling
- rolling deployments

Pro Tip (Important for Architect Interviews)

When answering **system design questions**, always follow this **structured approach**:

1 Clarify Requirements

Ask:

- traffic volume
- expected users
- read vs write ratio
- content size
- uptime requirements

2 Define Architecture Layers

Explain:

- CDN
- application layer
- caching layer
- database layer

3️⃣ Explain Scaling Strategy

Example:

- horizontal scaling
- caching
- database replicas

4️⃣ Discuss Trade-offs

Example:

- Drupal multisite vs separate instances
- Redis vs Memcached
- Solr vs Elasticsearch

5️⃣ Mention Monitoring

Example:

- NewRelic
- Datadog
- Prometheus

1. Explain Drupal Render Pipeline in Detail

What interviewers expect

Explain how Drupal converts a request into HTML.

Flow:

```
HTTP Request
  |
Symfony Kernel
  |
Routing System
  |
Controller
  |
Render Array
  |
Render API
  |
```

```
Twig Templates
  |
HTML Response
```

Key components:

- Render arrays
- Bubbleable metadata
- Cache contexts
- Twig rendering

2. What is Bubbleable Metadata in Drupal?

Bubbleable metadata ensures caching information propagates upward in the render tree.

Includes:

- cache tags
- cache contexts
- cache max-age

Example:

```
Cache Tags: node:1
Cache Context: user.permissions
Cache Max Age: 3600
```

3. Explain Drupal Cache Invalidation Architecture

Drupal uses **cache tags**.

Example:

```
node:1
taxonomy_term:5
user:3
```

When an entity updates:

node:1 → invalidates related caches

Advantages:

- precise cache clearing
- high performance

4. Difference Between Cache Contexts and Cache Tags

Feature	Cache Context	Cache Tag
Purpose	Vary cache by condition	Invalidate cache
Example	user.role	node:1

Example:

Cache Context: user.roles
Cache Tag: node:5

5. How Does Drupal Dynamic Page Cache Work?

Dynamic page cache caches pages **even for logged-in users**.

It varies cache by:

- user roles
- session contexts
- permissions

6. Explain Lazy Builders in Drupal

Lazy builders defer expensive rendering.

Example use cases:

- user-specific data
- cart details
- notifications

Benefits:

- faster page rendering
- personalized caching

7. When Should You Use Event Subscribers Instead of Hooks?

Hooks are **procedural**, event subscribers are **OOP-based**.

Use event subscribers when:

- working with Symfony events
- building modular architecture
- replacing legacy hooks

Example event:

KernelEvents::REQUEST

8. Explain Drupal Plugin Discovery Mechanism

Drupal plugins are discovered via:

Annotation
YAML definitions
Plugin managers

Example plugins:

- blocks
- field widgets
- field formatters
- image effects

9. What is the Drupal Service Container?

Drupal uses **Symfony Dependency Injection container**.

Benefits:

- loose coupling
- testability
- reusable services

Example service definition:

```
services:
 mymodule.service:
   class: Drupal\mymodule\Service\Example
```

10. Explain Drupal Dependency Injection Best Practices

Best practice:

constructor injection

Avoid:

\Drupal::service()

Reason:

- improves testing
- cleaner architecture

11. Explain Drupal Entity Architecture

Entities include:

Content Entity
Config Entity

Content entity example:

- node
- user
- taxonomy

Config entity example:

- view
- image style

12. How Would You Design a Custom Content Entity?

Steps:

1. Define entity annotation
2. Define base fields
3. Implement storage handler
4. Add forms
5. Add permissions

13. How Does Drupal Handle Access Control?

Access layers:

Route Access
Entity Access
Field Access
User Permissions

14. Explain Drupal Request Lifecycle

Flow:

Request
|

```
Routing
|
Controller
|
Render Array
|
Render Pipeline
|
Response
```

15. Explain Drupal Queue API Architecture

Queue API handles **asynchronous processing**.

Example tasks:

- sending emails
- large imports
- background jobs

Flow:

Create Item → Queue Worker → Process

16. Explain Drupal Cron System

Cron runs scheduled tasks like:

- clearing caches
- sending emails
- processing queues

Best practice:

Use **system cron + Drush cron**.

17. Explain Drupal Search Architecture

Large sites use:

```
Search API
   |
Solr / Elasticsearch
```

Advantages:

- scalable indexing

- faceted search
- high performance

18. How Would You Architect Drupal for 100M Content Items?

Key strategies:

- Solr indexing
- Redis caching
- sharded database
- optimized Views queries

19. How Would You Integrate Drupal With Microservices?

Approach:

```
Drupal CMS
  |
API Gateway
  |
Microservices
```

Communication patterns:

- REST
- GraphQL
- event queues

20. How Do You Design Drupal for API-first Architecture?

Use:

- JSON:API
- GraphQL
- OAuth authentication
- rate limiting

21. Explain Enterprise Drupal Governance

Large enterprises require:

- coding standards
- architecture guidelines
- module review processes
- deployment standards

22. How Do You Manage Drupal Technical Debt?

Strategies:

- regular upgrades
- code refactoring
- dependency updates
- architecture reviews

23. How Do You Handle Large Drupal Deployments?

Best practices:

Git based deployments
Composer builds
Config imports
Database updates

24. Explain Drupal Configuration Management Deeply

Drupal stores configuration in:

YAML files

Deployment:

drush config-export
drush config-import

Use:

Config Split

for environment differences.

25. Explain Drupal Performance Optimization Strategy

Layers:

Application

- render caching
- lazy builders

Infrastructure

- Redis
- Varnish

Edge

- CDN

1️⃣ Redis

What it is:
An **in-memory data store** (not just a cache)

Best for:

- Application-level caching
- Sessions, tokens, queues, counters
- Complex data structures

Key features:

- Supports **data structures**: strings, hashes, lists, sets, sorted sets
- Can **persist data to disk** (optional)
- Supports **TTL**, pub/sub, transactions
- Can be used as a **primary database** in some cases

Typical use cases:

- User sessions
- Rate limiting
- Job queues
- Cached API responses
- Real-time analytics

Pros:
✅ Very powerful
✅ Persistence option
✅ Rich data types

Cons:
❌ More memory usage
❌ Slightly more complex to manage

2️⃣ Memcached

What it is:
A **simple in-memory key–value cache**

Best for:

- Fast, temporary caching
- Reducing database load

Key features:

- Stores only **key** → **value** pairs
- No persistence (data is lost on restart)
- Extremely fast
- Simple architecture

Typical use cases:

- Caching database query results
- Page fragments
- Temporary objects

Pros:
✅ Super fast
✅ Simple and lightweight
✅ Easy to scale horizontally

Cons:
❌ No persistence
❌ No advanced data structures
❌ No replication

3️⃣ Varnish

What it is:
An **HTTP reverse proxy cache** (not an object cache)

Best for:

- Caching **entire HTTP responses**
- Speeding up websites dramatically

Key features:

- Sits **in front of web servers**
- Caches full pages and HTTP responses
- Uses VCL (Varnish Configuration Language)
- Excellent for anonymous traffic

Typical use cases:

- Full-page caching
- High-traffic websites
- CDN-like behavior (but on your server)

Pros:
✅ Massive performance boost
✅ Reduces backend load
✅ Great for read-heavy traffic

Cons:
❌ Not for application logic
❌ Not useful for logged-in users without customization

🔥 Side-by-side Comparison

Feature	Redis	Memcached	Varnish
Cache layer	Application	Application	HTTP/Web
Data types	Rich	Simple key-value	HTTP responses
Persistence	Optional	❌ No	❌ No
Use for sessions	✅ Yes	⚠️ Limited	❌ No
Full page cache	❌ No	❌ No	✅ Yes
Complexity	Medium	Low	Medium
Speed	Very fast	Extremely fast	Extremely fast

🧠 When should you use what?

- **Use Redis** when you need **logic + data structures + sessions**
- **Use Memcached** when you just want **blazing-fast, simple caching**
- **Use Varnish** when you want **full-page caching for high traffic**

👉 **Real-world setup (very common):**
Varnish + Redis

- Varnish → cache pages
- Redis → cache sessions & objects

To set up a CI/CD pipeline for a Spring Boot application using AWS services, you can follow these steps:

1. Version Control: Push your Spring Boot codebase to a repository like AWS CodeCommit (or GitHub/GitLab).

2. Build & Test (CI):

Use AWS CodeBuild to build the application.

Configure a buildspec.yml file to run Maven/Gradle commands for compiling, running unit tests, and packaging the JAR.

Store build artifacts in Amazon S3 or push Docker images to Amazon ECR (if containerized).

3. Deployment (CD):

Use AWS CodeDeploy to automate deployments.

If using EC2, deploy the JAR directly.

If using ECS/Fargate or EKS, update container images from ECR.

For serverless, deploy to AWS Lambda using API Gateway.

4. Pipeline Orchestration:

Set up AWS CodePipeline to connect all the stages: Source → Build → Test → Deploy.

Configure triggers so that whenever you push code to the main branch, the pipeline automatically executes.

5. Additional Best Practices:

Use IAM roles & policies for secure access.

Add CloudWatch monitoring and logging for health checks.

Optionally integrate SonarQube or CodeGuru for code quality.

Enable Blue-Green or Rolling deployments for zero downtime.
